Decision Boundary

In order to get our discrete 0 or 1 classification, we can translate the output of the hypothesis function as follows:

$$h_{ heta}(x) \geq 0.5
ightarrow y = 1$$

$$h_{ heta}(x) < 0.5
ightarrow y = 0$$

The way our logistic function g behaves is that when its input is greater than or equal to zero, its output is greater than or equal to 0.5:

$$g(z) \ge 0.5$$
 when $z > 0$

Remember.

$$z=0, e^0=1\Rightarrow g(z)=1/2 \ z o\infty, e^{-\infty} o 0\Rightarrow g(z)=1 \ z o -\infty, e^{\infty} o\infty\Rightarrow g(z)=0$$

So if our input to g is $\theta^T X$, then that means:

$$h_{ heta}(x) = g(heta^T x) \geq 0.5 \ when \ heta^T x \geq 0$$

From these statements we can now say:

$$heta^T x \geq 0 \Rightarrow y = 1$$

 $heta^T x < 0 \Rightarrow y = 0$

The **decision boundary** is the line that separates the area where y = 0 and where y = 1. It is created by our hypothesis function.

Example:

$$egin{aligned} heta &= egin{bmatrix} 5 \ -1 \ 0 \end{bmatrix} \ y &= 1 \ if \ 5 + (-1)x_1 + 0x_2 \geq 0 \ 5 - x_1 \geq 0 \ -x_1 \geq -5 \ x_1 \leq 5 \end{aligned}$$

In this case, our decision boundary is a straight vertical line placed on the graph where $x_1=5$, and everything to the left of that denotes y = 1, while everything to the right denotes y = 0.

Again, the input to the sigmoid function g(z) (e.g. $\theta^T X$) doesn't need to be linear, and could be a function that describes a circle (e.g. $z=\theta_0+\theta_1x_1^2+\theta_2x_2^2$) or any shape to fit our data.

Mark as completed
